Xenon supply & enrichment

$\beta\beta$ trends (updated Elliott/Vogel plot by Vogel)

History of the $0\nu\beta\beta$ decay

Moore's law of $\beta\beta$ decay

Historically, there are > 100 experimental limits on $T_{1/2}$ of the $0\nu\beta\beta$ decay. Here are the records expressed as limits on $\langle m_{\beta\beta} \rangle$ using one set of nuclear matrix elements (RQRPA of Simkovic et al. 2009.)

During the last decade the complexity and cost of experiments has increased very dramatically. The slope constant is now leveling off!

Perspective

- NLDBD has entered a new era:
“Maybe not big/good enough to succeed,
but too expensive to fail”
- Failure: *background-limited result*
- Energy resolution, shielding, radio-purity,...
not (yet) sufficient to reject all backgrounds
- A **discovery class** experiment should aim for
zero background well into inverted domain

Sensitivity, Background and Exposure

Various Levels of Confidence in a Result

- **Preponderance of the evidence:**
 - Correct peak energy with no 2-v contamination
 - Single-site energy deposit
 - Proper detector distributions (spatial, temporal)
 - Rate scales with isotope fraction
- **Beyond a reasonable doubt:**
 - Observe the two-electron nature of the event
 - Measure kinematic dist. (energy sharing, opening angle)
 - Observe the excited state decay
 - See the process consistently in several isotopes
- **Smoking Guns:**
 - Observe the daughter atom
 - A background-free positive result with enriched isotope – AND:
 - See no peak with depleted isotope – no other changes to detector

Why Xenon Gas?

- **Excellent intrinsic energy resolution:**
 $\delta E/E < 3 \times 10^{-3}$ FWHM at ^{136}Xe $Q_{\beta\beta}$ (2457 KeV)
This will be hard to approach in real-life, but maybe 5×10^{-3} FWHM
- **Topology available for background rejection**
Single electrons (γ -rays) create one endpoint blob
Double-beta decay events create two endpoint blobs
- **Gas phase allows molecular admixtures**
Reduced diffusion for better tracking, event integrity, MS measurement, possible wavelength-shifting, Penning effect, ...
- **New idea for daughter identification...**
Barium tagging at high pressure...! ??

NEXT: A light TPC

EL mode is essential to get lineal gain, therefore avoiding avalanche fluctuations and fully exploiting the excellent Fano factor in gas

- It is a High Pressure Xenon (HPXe) TPC operating in EL mode.
- It is filled with 100 kg of Xenon enriched at 90% in Xe-136 (in stock) at a pressure of 15 bar.
- The event energy is integrated by a plane of radiopure PMTs located behind a transparent cathode (energy plane), which also provide t_0 .
- The event topology is reconstructed by a plane of radiopure silicon pixels (MPPCs) (tracking plane).

NEXT 100 kg detector at LSC: main features

NEXT-100 Pressure Vessel

23 May 2013

WINP 2015

10

NEXT at LSC

Infrastructures: platform, lead castle, gas system, emergency recovery system, completed. First phase of experiment starts in 2015. In stock, 100 kg of enriched xenon and 100 kg of depleted xenon.

NEXT Platform and Pb Castle at LSC

**65 t of Pb sheets from OPERA
disassembled bricks received as a loan
(for all the duration of NEXT) by INFN**

**Pb bricks (mainly of standard form)
produced by Tecnibusa
(5% loss)**

Three deliveries

- 7 July**
- 11 August**
- 29 September**

Cleaning and assembly made by NEXT

NEXT Expected Performance

Systematic assay of ALL detector components at the LSC HPGe facility
Development of full MonteCarlo simulations

Selection criterion	$\beta\beta 0\nu$	$\beta\beta 2\nu$	^{208}Tl	^{214}Bi

NEXT-DBDM. Energy resolution

NEXT-DBDM obtains an extraordinary energy resolution: 1.04% at Cs-137 peak (about 0.53% @ Q_{bb})
No tracking yet. Impose hard fiducial cut which in practice selects only events in the center of the chamber.

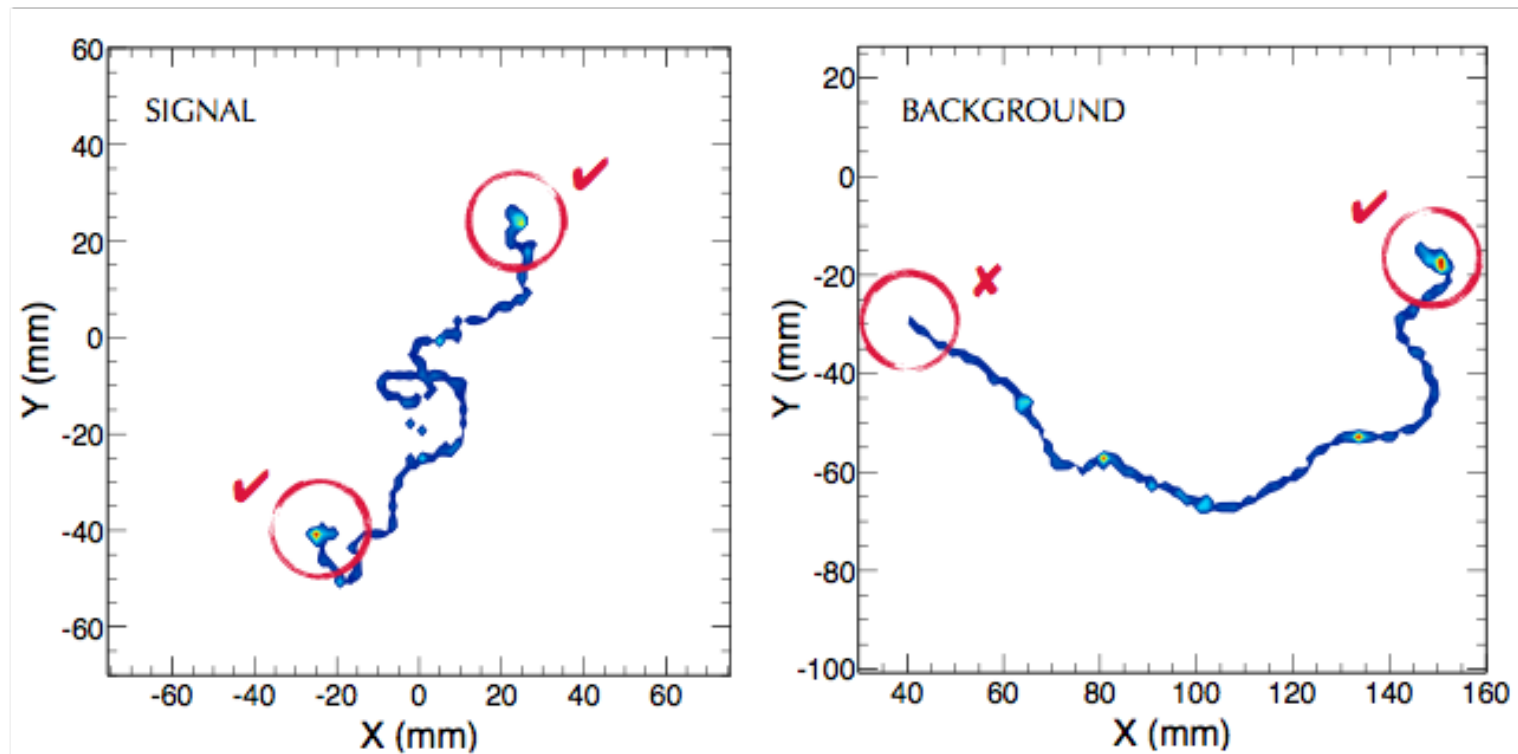

A typical ^{137}Cs γ waveform (sum of 19 PMTs)
~300,000 detected photoelectrons

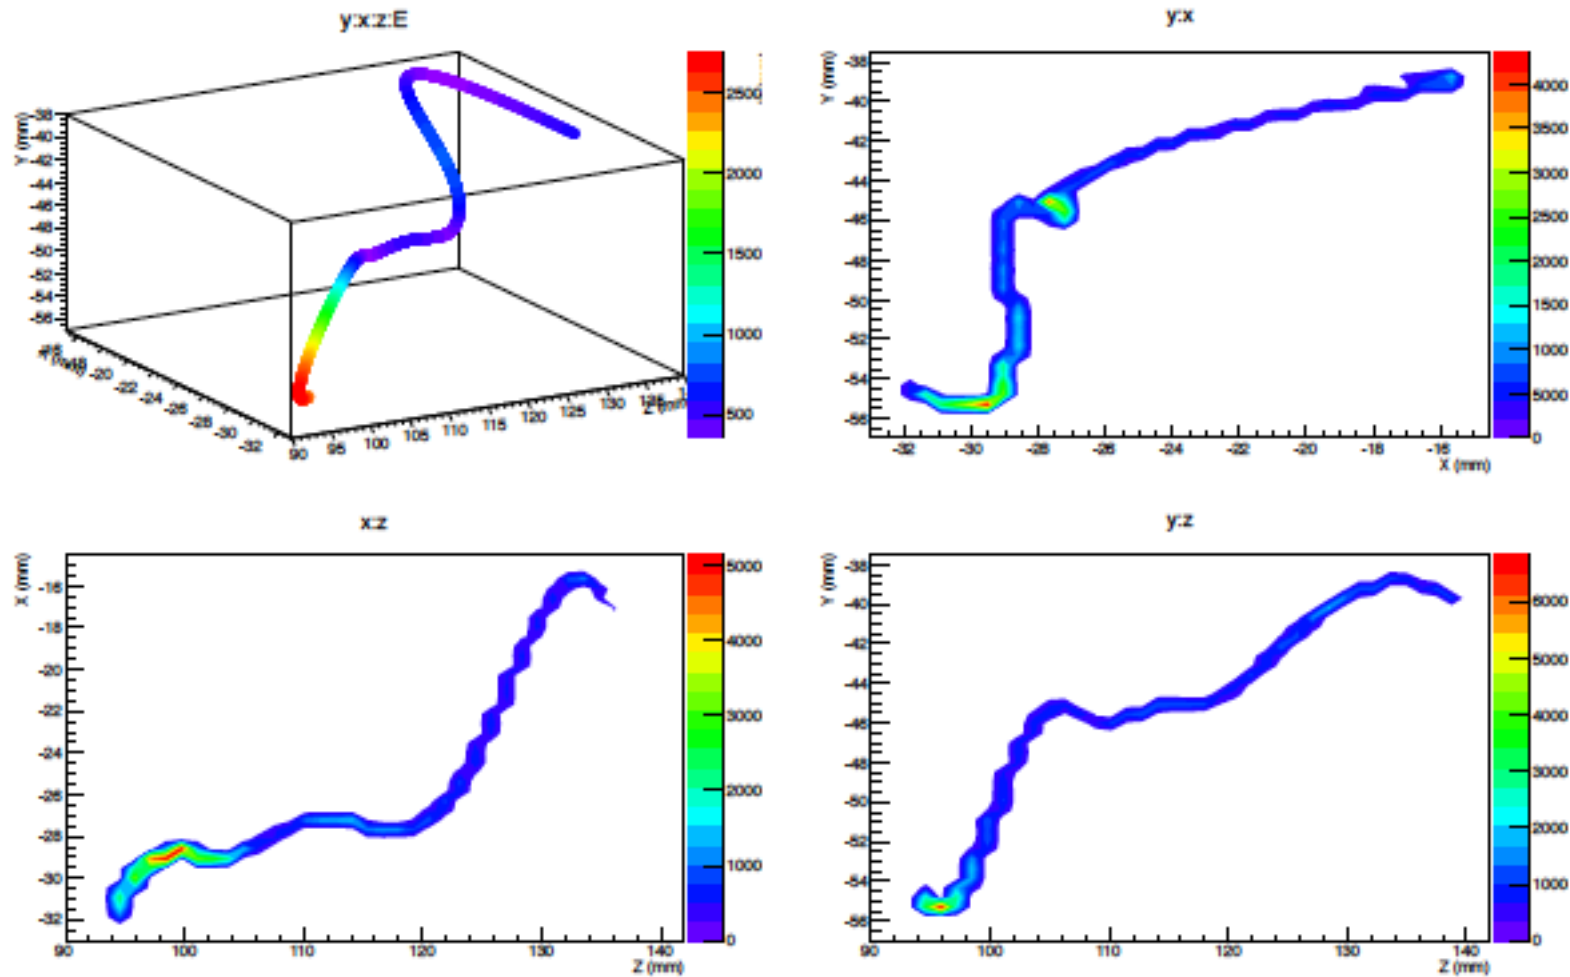

The x-ray peaks at ~ 30 keV are captured precisely

Topological signature - simulation

DATA: Real track from ^{137}Cs γ -ray – reconstructed with SiPMs

Identify the barium daughter by optical spectroscopy

(M.Moe PRC44 (1991) 931)

Ba⁺ system best studied
(Neuhauser, Hohenstatt,
Toshek, Dehmelt 1980)

Single ions can be detected
from a photon rate of 10⁷/s

Triplet state is quenched
in dense gas

Can excite with blue,
look only for red

Xenon's barium daughter

- In the decay, barium is strongly ionized by the nascent electrons emerging from the nucleus.
- Ba^{++} is the expected outcome, after partial neutralization occurs by electron capture from neutral xenon (ionization potential 12.14 eV).
- Process stops at Ba^{++} because the ionization potential of Ba^{++} is 10.04 eV; it can't take another electron from a xenon atom.
- For the Ba^+ spectroscopy to work, another electron must come from somewhere.
- Ba^+ must be transported to low-pressure trap

Might there be another way?

- Perhaps. The technique of **Single Molecule Fluorescent Imaging** may be adaptable here.
- My idea is to exploit a remarkable chemical effect: the **transformation** of non-fluorescent precursors into a robust fluorescent state by capture and chelation of doubly ionized alkaline earth elements such as Ca^{++}

Might there be another way?

- Perhaps. The technique of **Single Molecule Fluorescent Imaging** may be adaptable here.
- My idea is to exploit a remarkable chemical effect: the **transformation** of non-fluorescent precursors into a robust fluorescent state by capture and chelation of doubly ionized alkaline earth elements such as Ca^{++}
- Maybe Ba^{++} too! **Ca and Ba are congeners**

Conformal changes in Fluo-3

Once Ca^{++} is captured by Fluo-3, its responsiveness to external excitation increases by a factor of 60 -80. Two-photon excitation with IR is also possible

This might work for Barium as well since barium and calcium are congeners. Fluorophores exist for Pb^{++} , Hg^{++} , Cu^{++} ...)

2014 Nobel Prize in Chemistry awarded to three physicists for developing SMFI

A TPC with a fluorescent cathode?

- One can imagine a cathode surface coated with untransformed fluorophores waiting to respond strongly after capture of one Ba^{++} .

A TPC with a fluorescent cathode?

- One can imagine a cathode surface coated with untransformed fluorophores waiting to respond strongly after capture of one Ba^{++} .
- One can imagine that the cathode surface is a dielectric belt that transports at a few mm/s the latent image to a line imager.

A TPC with a fluorescent cathode?

- One can imagine a cathode surface coated with untransformed fluorophores waiting to respond strongly after capture of one Ba^{++} .
- One can imagine that the cathode surface is a dielectric belt that transports at a few mm/s the latent image to a line imager.
- Ionization electrons liberated by the decay electrons provide a 3-D image of the event, and also the needed energy resolution, *a la* NEXT

HIGH PRESSURE XENON GAS ELECTROLUMINESCENT TPC
WITH SINGLE MOLECULE FLUORESCENT IMAGING OF BARIUM DAUGHTER

Summary & Perspective

- The need for a genuine **advance** is imperative.
- Is only a **background-free** experiment justifiable?
- **Gas-phase** Xenon offers flexibility and opportunities.
- **NEXT** is phased: 10 → 100 → ¿¿ 1000 ?? kg
- **NEXT** is somewhat behind more conventional techniques, but may hold **keys** to ultimate success.

Thank you

Energy resolution at $Q_{\beta\beta} = 2457$ keV

$$\delta E/E = 2.35 \cdot (F \cdot W/Q)^{1/2}$$

- $F \equiv$ Fano factor (HPXe) : $F = 0.15$
 - $w \equiv$ Average energy per ion pair: $w \sim 25$ eV
 - $Q \equiv$ Energy deposited from $^{136}\text{Xe} \rightarrow ^{136}\text{Ba}$:
- $N = Q/w \sim 100,000$ primary electrons
- $\sigma_N = (F \cdot N)^{1/2} \sim 124$ electrons rms!

$\delta E/E = 0.28\% \text{ FWHM}$	intrinsic HPXe
------------------------------------	-----------------------

23 May 2013

WINP 2015

- $\beta\beta$ decay: Rare transition between same A nuclei
 - Energetically allowed for some even-even nuclei

- $(Z,A) \rightarrow (Z+2,A) + e^- + \bar{\nu}_1 + e^- + \bar{\nu}_2$
- $(Z,A) \rightarrow (Z+2,A) + e^- + e^-$
- $(Z,A) \rightarrow (Z+2,A) + e^- + e^- + \chi$

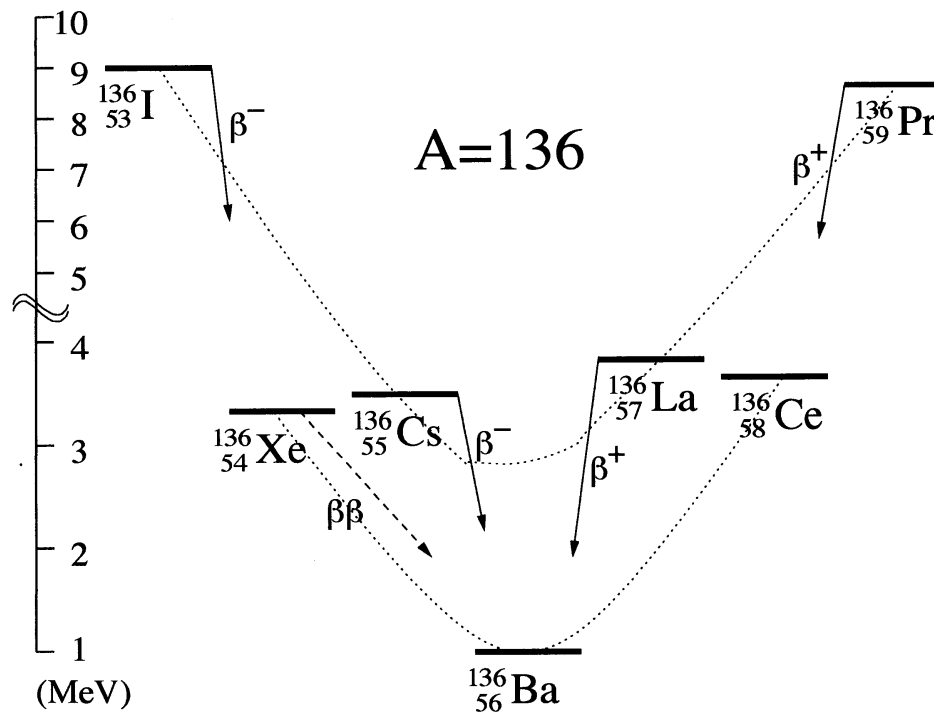

Figure 2.1: Simplified atomic mass scheme for nuclei with $A=136$. The parabolae connecting the odd-odd and even-even nuclei are shown. While ^{136}Xe is stable to ordinary beta decay, it can decay into ^{136}Ba by double-beta decay.

The neutrino effective mass m_ν

- Decay rate $\approx m_\nu^2$

$$\left[T_{1/2}^{0\nu}(0^+ \rightarrow 0^+)\right]^{-1} = G^{0\nu}(E_0, Z) \left| M_{\text{GT}}^{0\nu} - \frac{g_V^2}{g_A^2} M_{\text{F}}^{0\nu} \right|^2 \langle m_\nu \rangle^2$$

- Effective mass m_ν depends on phases:

$$\langle m_\nu \rangle^2 = \left| \sum_i^N U_{ei}^2 m_i \right|^2 = \left| \sum_i^N |U_{ei}|^2 e^{i\alpha_i} m_i \right|^2$$

Experimental Parameters

$$\langle m_{\beta\beta} \rangle \leq (2.50 \times 10^{-5} \text{ meV}) \sqrt{\frac{W}{fx\varepsilon G_{0\nu} |M_{0\nu}|^2}} \left[\frac{b\Delta E}{MT} \right]^{\frac{1}{4}}$$

- W – molecular weight of source
- f – isotopic abundance
- x – number of bb isotopes per molecule
- ε – detector efficiency
- $G_{0\nu}$ – decay phase space
- $|M_{0\nu}|$ - matrix element
- b – background in counts/keV-kg-y
- ΔE – energy window in keV
- M – mass of source in kg
- T – counting time in years

- When comparing isotopes, don't forget W, favors low A. $G_{0\nu}$ favors high A.
- QRPA has more A dependence than SM.

Isotope	$\sqrt{W/(G_{0\nu} M_{0\nu} ^2)} \times 10^7$
Ge	2.4(QRPA) 4.7(SM)
TeO ₂	1.9(QRPA) 3.1(SM)
Xe	2.4(QRPA) 3.3(SM)

The Experimental Challenges

Maximize Rate/Minimize Background

$$\langle m_{\beta\beta} \rangle \propto \left(\frac{b\Delta E}{Mt_{live}} \right)^{\frac{1}{4}}$$

b = background/keV

ΔE = Energy ROI

M = active isotopic mass

t_{live} = graduate students

Large Mass (~ 1 ton)

Large Q value, fast $\beta\beta(0\nu)$

Good source radiopurity

Demonstrated technology

Ease of operation

High isotopic abundance

Easy enrichment

Small volume, source = detector

Good energy resolution

Slow $\beta\beta(2\nu)$ rate

Identify daughter in real time

Event reconstruction

Nuclear theory

Energy resolution

0,5 % FWHM

1,0 % FWHM

4,0 % FWHM

10 % FWHM

Signal and background:

- Signal: mv \sim 200 meV and an exposure of 5 ton year.
- Background 1 count/keV/ton/year.

Figure from Mike Moe

Splitting the window, or in the case of high-event rates, fitting the spectrum.

$\beta\beta$ Sensitivity

(mixing parameters from arXiv:1106.6028)

Even a null result will constrain the mass spectrum possibilities!

A $m_{\beta\beta}$ limit of ~ 20 meV would exclude Majorana neutrinos in an inverted hierarchy.

Background model dominated by limits rather than by actual values
